

02A

OPEN2ARTIST

# Identity that moves with the artist.

A Bitcoin-native identity and trust layer for live music. Artists, venues, promoters, labels, events and albums, each with an ID they hold in their own keys.

September 2026

Pitch deck · v1

The problem

# Live music runs on identity that nobody owns.

The same artist is five different records in five different systems. None of them belongs to the artist, and none proves the artist agreed to be matched with the others.

Streaming platform A  
4pQz...7Lm2

Streaming platform B  
1093...2287

Analytics vendor  
art\_55...921

Open catalog

Rights registry  
0000 0004 ...

Held by the artist  
none

For venues and promoters the picture is worse: the same tour has different names and IDs in every country it touches.

Where this comes from

# We found the problem inside our own data.

Building CT-GOT, our ticket-sales forecasting model, we had to reconcile millions of ticket and event sales across Central America and the Caribbean.

Every artist had to be matched across four or five platform IDs that disagreed on canonical names, song authorship and album records. Venue and promoter names for the same tour were inconsistent from one country to the next. A centralized registry did not solve it, because a catalog entry proves nothing about who controls the name.

4-5

platform IDs per artist, none interchangeable, none authorized by the artist

1

answer we needed: who is this, and who is allowed to say so

The team was already building SplitNight, an RGB settlement application on Bitcoin. 02A is the identity layer that work was missing.

Why it matters

# A booking is a chain of trust with no verifiable link.

## Fake promoters

Anyone can announce a show with an artist's name. There is no signature to check, so fans, venues and press take it on faith.

## Spoofed profiles

An artist's identity is a platform account that can be hacked, cloned or suspended. Losing it means losing the history behind it.

## Disputes with no record

Who confirmed the date? Who authorized the poster? Who gets paid? Today the answer lives in emails and screenshots.

Every application that consumes a wrong association spreads it. A shared, verifiable record is how the ecosystem detects and corrects mistakes instead of inheriting them.

# Your key. Your identity. Your evidence.

A public identity rooted in Bitcoin, held in the owner's wallet, with a history any compatible wallet can verify on its own.

What an EntityID is

# One ID per participant. Six kinds of participant.

Each identity is rooted in its own key. Day-to-day signing keys rotate without erasing the public ID. An event or an album lives in the responsible wallet but stays an independent identity of its own.

---

## Artist

Signs claims, attestations and authorizations

---

## Venue

Confirms performances and bookings

---

## Promoter

Confirms dates and representation

---

## Label

Endorses catalog and associations

---

## Event

A show with a versioned, hashed manifest

---

## Album

A work with a versioned, hashed manifest

A human-readable name is a claim backed by evidence, not a username locked forever by whoever typed it first. Wallets show the evidence, the conflicts and the chronology, and apply their own policy.

How it works

# Three layers. Three questions. Never collapsed into one.

## Bitcoin

Orders the facts and seals them. Once anchored, the history cannot be rewritten.

answers: when, and in what order  
does not answer: who

## RGB

Carries the identity lifecycle as client-side state: genesis, key rotation, recovery, revocation. Private by default, validated locally.

answers: is this history valid  
does not answer: is this the real artist

## O2A

Checks who was authorized to sign, evaluates the evidence, and applies an explicit, versioned policy.

answers: valid, invalid, conflicting,  
incomplete  
and shows exactly why

**Same evidence. Same result. Anywhere.** Two wallets that never met reach the same conclusion from the same package, without asking us.

Day one for an artist

# Four things you can do with an identity you own.

01

## Create it from your own keys

Derived in your wallet, separate from any bitcoin you spend. No platform approves it; no platform can take it away.

03

## Hand a new venue your proof package

One file with your history and evidence. The venue's wallet verifies it in seconds and applies its own acceptance rules.

02

## Sign a show together with the venue

You attest the date, the venue attests the booking. Two signatures, one anchored record that the promoter, the press and the fans can check.

04

## Approve a use and get paid for it

A promotional mention, a catalog link, a tour-date integration: a signed permission carrying a payment in satoshis, at the moment of authorization.

# No token. No new chain. Standards that already exist.

## Bitcoin

The most credible public timestamp and settlement layer there is. O2A uses it for ordering and sealing, nothing more. Identity keys never spend bitcoin.

## RGB

Client-side validation on Bitcoin. State stays with its owner, scales off-chain, and is validated by the recipient. Built with the RGB working group, not around it.

## Open standards

BIP340 signatures and BIP85 key derivation. Mappings to existing identifiers such as ISNI and DDEX party records. Aligned with W3C Verifiable Credentials 2.0.

---

Registries and catalogs become rebuildable projections over evidence. Any operator can index it; none of them is the source of truth.

Existing platform IDs are linked, not replaced. O2A adds the missing piece: a portable record of who authorized the link.

Where it fits

# The identity layer of an operating system for live events.

Cortex finances live events from artist offer to post-event settlement. Every step needs to know who it is dealing with. O2A is that answer, and it is open for anyone else to build on.

Where we are today

# Running on Bitcoin test networks. Verified by independent code.

12

signed protocol objects with canonical encoding and fail-closed conformance checkers

3

independent implementations of the key-derivation profile, all producing identical keys

2

independent validators agreeing byte for byte on a live identity genesis and key rotation anchored on Bitcoin

5

contributions filed with the RGB working group, including a fix already published as a branch

1

signet node and Electrum server synced and accepted for the live demonstration

v0.1

draft specification with architecture decisions, threat boundaries and an audited dependency policy

Everything above is reproducible from two public repositories with content-addressed evidence bundles.

# From a live demo to a mainnet identity, gate by gate.

The first pilot

# One city. One venue network. Numbers, not opinions.

## What we run

10 to 50 artists, venues and promoters in a market we already operate in. Real bookings, real attestations, a manual trust policy we tune with participants, and a simple registry anyone can rebuild from the evidence.

Our own ticketing operation is the first integrator, so the pilot starts with counterparties who already work together.

## What we measure

Time and manual steps to verify a new counterparty, with and without O2A. Which evidence participants can actually provide. Verification errors and unresolved disputes. The effort of managing keys and recovery.

For paid authorizations: willingness to participate, net revenue after fees, time from payment to usable grant.

A cryptographic demo proves the protocol. The pilot proves the workflow is worth adopting.

Why now

# The industry is asking the question. The rails are finally ready.

## Identity is on the agenda

In August 2026 the largest streaming platform named artist identity, profile protection and verification as a priority. Platform protections and portable evidence can now be tested side by side.

## The standards landed

W3C Verifiable Credentials 2.0 is a Recommendation. BIP340 and BIP85 are deployed in wallets today. There is nothing to invent at the cryptographic layer.

## RGB reached 0.12

Client-side validation on Bitcoin has a stable core and an active working group. We are already contributing fixes to it, which is the position you want when the final release ships.

---

And the first territory is one we know from the inside: the live-events market across Central America and the Caribbean, where cross-border tours make identity fragmentation an everyday cost.

## Team

# Operators of live events. Builders on Bitcoin since 2022.

---

## Jose Antonio Toriello

### General Partner

Leads Cortex and its investor product, PRONESYS, financing concert tours with short-term asset-backed notes.

---

## Gustavo "Goose" Gonzalez

### CTO

Runs the platform stack: ticketing, settlement and the SplitNight application on RGB.

---

## Edwin Kestler

### Chief Scientist

Author of CT-GOT and of the O2A protocol. Built a Lightning-connected arcade shown at Bitcoin Miami 2022; open-source work on GitHub, Hackaday and Hackster.

Cofounders of a ticketing platform operating across Central America and the Caribbean, with the sales data that made the identity problem visible in the first place.

Join the first network

# Identity opens the door. Evidence makes it useful.

## Pilot partners

Venues, promoters and artists ready to sign real bookings on the network in 2027.

## Builders

Wallet, RGB and identity engineers who want an open protocol with real users behind it.

## Capital

To ship the minimum wallet and run the first measured pilot through 2027.
